This study compares three paradigms for solving the Weighted Max-Cut problem: a Genetic Algorithm, a Graph Neural Network, and a tensor network approach using Density Matrix Renormalization Group. Evaluating graphs from 10 to 250 nodes, it analyzes solution quality, runtime, and memory usage. Results show trade-offs in scalability, efficiency, and approximation performance.

- [3] Francesco Pio Marino Simone Faro. Scaling grover's search for large solution spaces. HPDC '25: Proceedings of the 34th International Symposium on High-Performance Parallel and Distributed Computing, 2025.

This work improves Grover's algorithm for cases where valid solutions exceed half the search space, a regime where performance typically degrades. By virtually expanding the domain with auxiliary qubits and modifying the oracle, the method reduces effective solution density without increasing circuit depth. Simulations confirm improved reliability while preserving Grover's optimal asymptotic complexity.

- [4] Juan Ungredda and Juergen Branke. Bayesian optimisation for constrained problems. ACM Transactions on Modeling and Computer Simulation, Volume 34, Issue 2, 2024.

The paper introduces a constrained variant of the Knowledge Gradient acquisition function for Bayesian optimisation to handle expensive black-box problems with constraints. It uses a Gaussian process surrogate to sequentially select evaluations, empirically outperforming four state-of-the-art constrained

BO methods, and proves convergence to the true optimum in the infinite budget limit.
